

(a) Naive row-random split (80/20)

experiments within a publication ->

Experiments from a single publication land on BOTH sides of the split. Correlated features (same publication) leak from train into test.

(b) Citation-grouped split (80/20)

experiments within a publication ->

Each publication is wholly in train OR wholly in test. No within-citation leakage; generalisation error is measured against unseen literature, not unseen rows.
